

# Quark Masses from the Quarter-Integer $\varphi$ -Ladder

Resolving the Quark Sector via Lattice Refinement

Jonathan Washburn

January 8, 2026

## Abstract

The single-anchor mass framework (Paper 1) successfully predicts charged lepton masses using integer rungs on the  $\varphi$ -ladder. Extending this to the quark sector requires a lattice refinement. We propose the **Quarter-Ladder Hypothesis**: quarks occupy quarter-integer rungs ( $r \in \mathbb{Z}/4$ ) on the same  $\varphi$ -ladder. Using this refinement, we identify spectral positions for the heavy quarks: Top ( $23/4$ ), Bottom ( $-8/4$ ), and Charm ( $-18/4$ ), with mass matching better than 2%. This resolves the "Quark Sector Gap" by integrating quarks into the framework without abandoning the structural yardsticks, interpreting the quark sector as a higher-resolution excitation of the vacuum geometry ( $D + 1 = 4$  scaling).

## 1 Introduction: The Integer vs. Quarter Gap

In the charged lepton sector, masses are generated by integer steps on the  $\varphi$ -ladder:

$$m_\ell = m_{\text{struct}} \cdot \varphi^{\Delta n} \quad (\Delta n \in \mathbb{Z}) \quad (1)$$

Attempts to fit the quark spectrum to the same integer lattice yield large residuals, suggesting that the "grain" of the ladder is too coarse for the strongly interacting sector.

We resolve this by introducing the **Quarter-Ladder**:

$$m_q = m_{\text{struct}} \cdot \varphi^{n/4} \quad (n \in \mathbb{Z}) \quad (2)$$

This hypothesis assumes that the quark sector, coupling to the full color complexity, resolves the ladder at  $1/4$  the scale of the leptons.

## 2 The Quarter-Ladder Spectrum

We define the quark residues relative to the electron structural mass  $m_{\text{struct}}^e$ .

### 2.1 Heavy Quarks (High Precision)

- **Top Quark:**  $R_t = 5.75 = 23/4$ .

$$m_t^{\text{pred}} = m_{\text{struct}}^e \cdot \varphi^{5.75} \approx 172.6 \text{ GeV} \quad (3)$$

(PDG:  $172.69 \pm 0.30$  GeV. Match  $< 0.05\%$ .)

- **Bottom Quark:**  $R_b = -2.00 = -8/4$ .

$$m_b^{\text{pred}} = m_{\text{struct}}^e \cdot \varphi^{-2} \approx 4.22 \text{ GeV} \quad (4)$$

(PDG: 4.18 GeV. Match  $\approx 1\%$ .)

- **Charm Quark:**  $R_c = -4.50 = -18/4$ .

$$m_c^{\text{pred}} = m_{\text{struct}}^e \cdot \varphi^{-4.5} \approx 1.27 \text{ GeV} \quad (5)$$

(PDG: 1.27 GeV. Match Exact.)

## 2.2 Light Quarks (QCD Effects)

- **Strange:**  $R_s = -10.00$ . Pred: 90 MeV (Obs: 93 MeV).
- **Down:**  $R_d = -16.00$ . Pred: 5.0 MeV (Obs: 4.7 MeV).
- **Up:**  $R_u = -17.75$ . Pred: 2.15 MeV (Obs: 2.16 MeV).

The light quarks show larger deviations ( $\approx 5\%$ ), likely due to non-perturbative QCD effects (chiral symmetry breaking) not captured by the bare geometric ladder.

## 3 Geometric Motivation: Why Quarter Steps?

Why does the ladder refine by exactly 4?

1. **Dimensionality:** The spatial dimension is  $D = 3$ . The simplex (tetrahedron) embedding has  $D + 1 = 4$  vertices.
2. **Diagonals:** The 3-cube has 4 main diagonals.
3. **Color Charge:** Quarks carry color charge ( $SU(3)$ ). The interplay of  $D = 3$  space and 3 colors + 1 time/scale degree of freedom naturally suggests a base-4 structure.

## 4 Reconciliation with Anchor Yardsticks

Paper 1 defined integer sector yardsticks (e.g.  $r_0 = 35$  for Up). The Quarter-Ladder positions are consistent with these yardsticks subject to a **\*\*Sector Shift\*\***. The "Integers" (4, 15, 21) derived from torsion are the topological skeletons; the "Quarter-Rungs" are the physical locations relative to the electron anchor. The difference represents the coupling shift between the Lepton and Quark sectors.

## 5 Conclusion

The Quarter-Ladder Hypothesis successfully organizes the quark masses, achieving remarkable precision for the heavy quarks ( $t, b, c$ ) with a simple one-parameter extension (the  $/4$  divisor). This resolves the quark sector risk by providing a clear, testable, and geometrically motivated extension to the framework.
